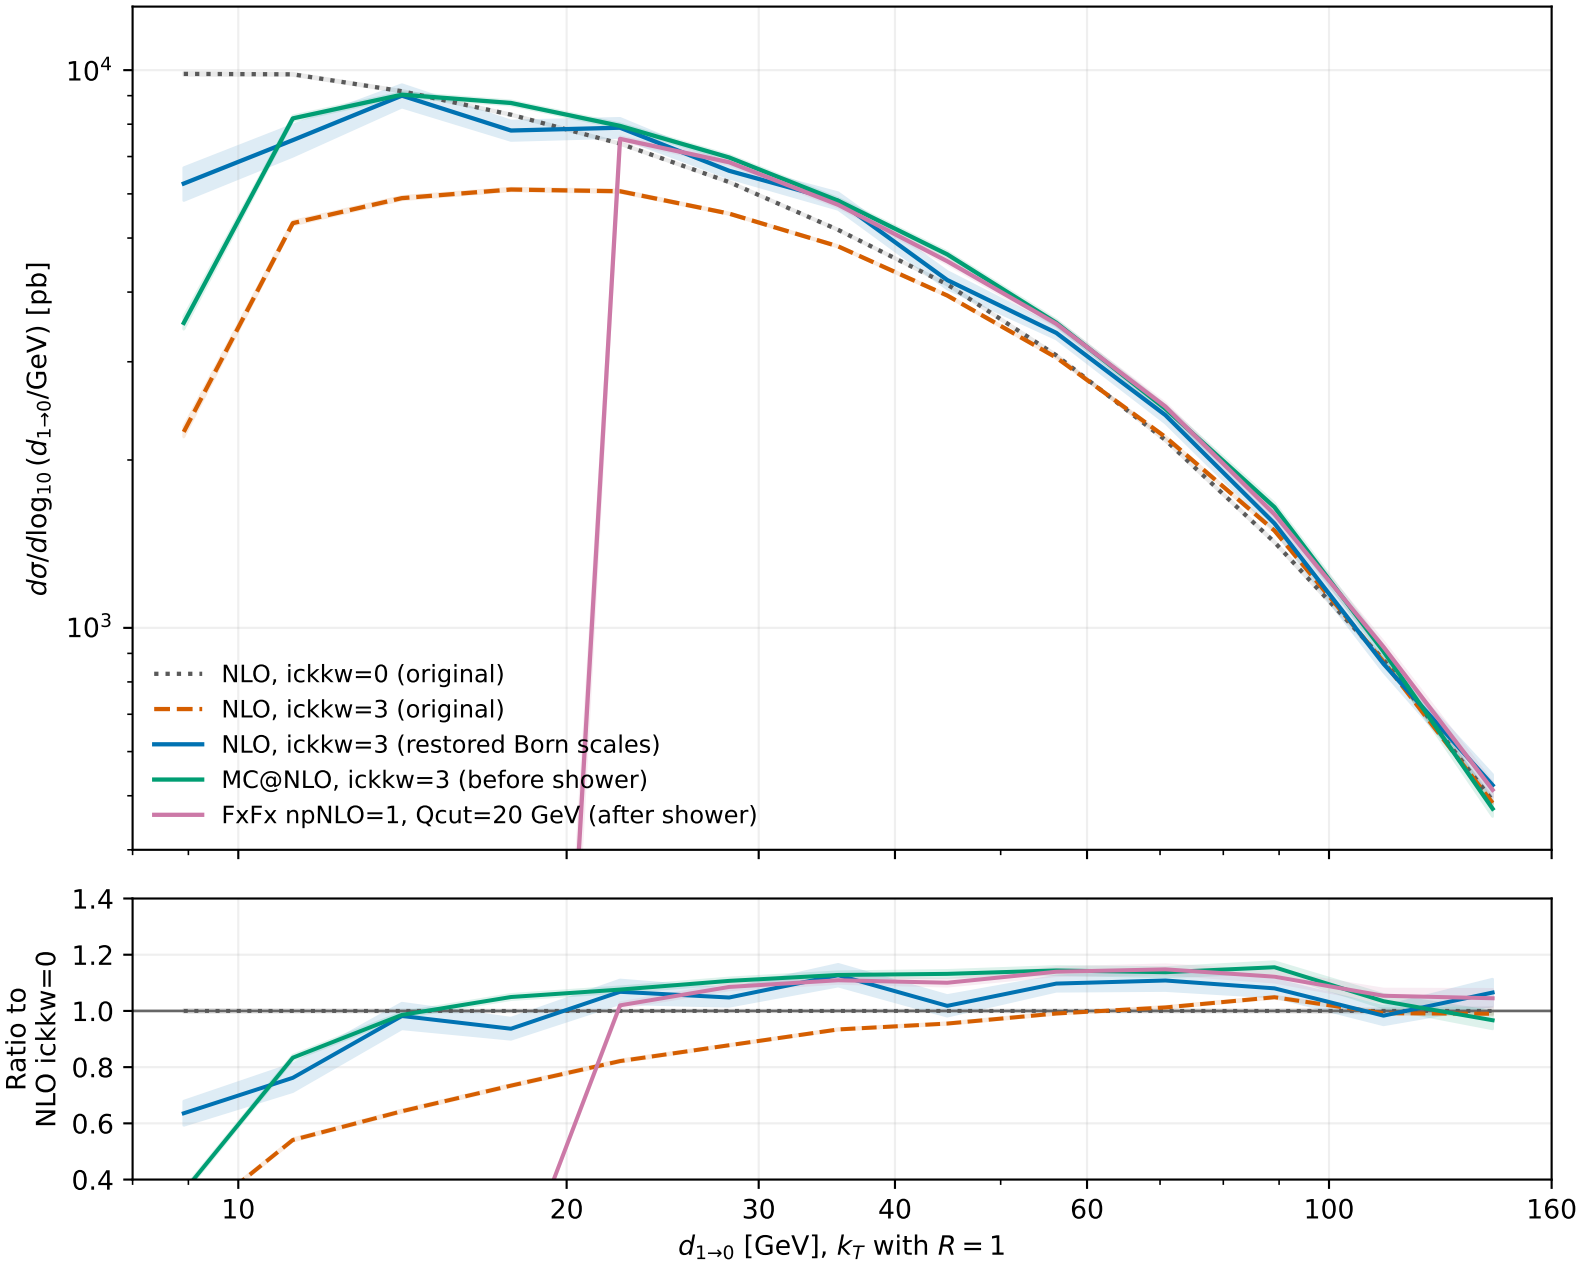
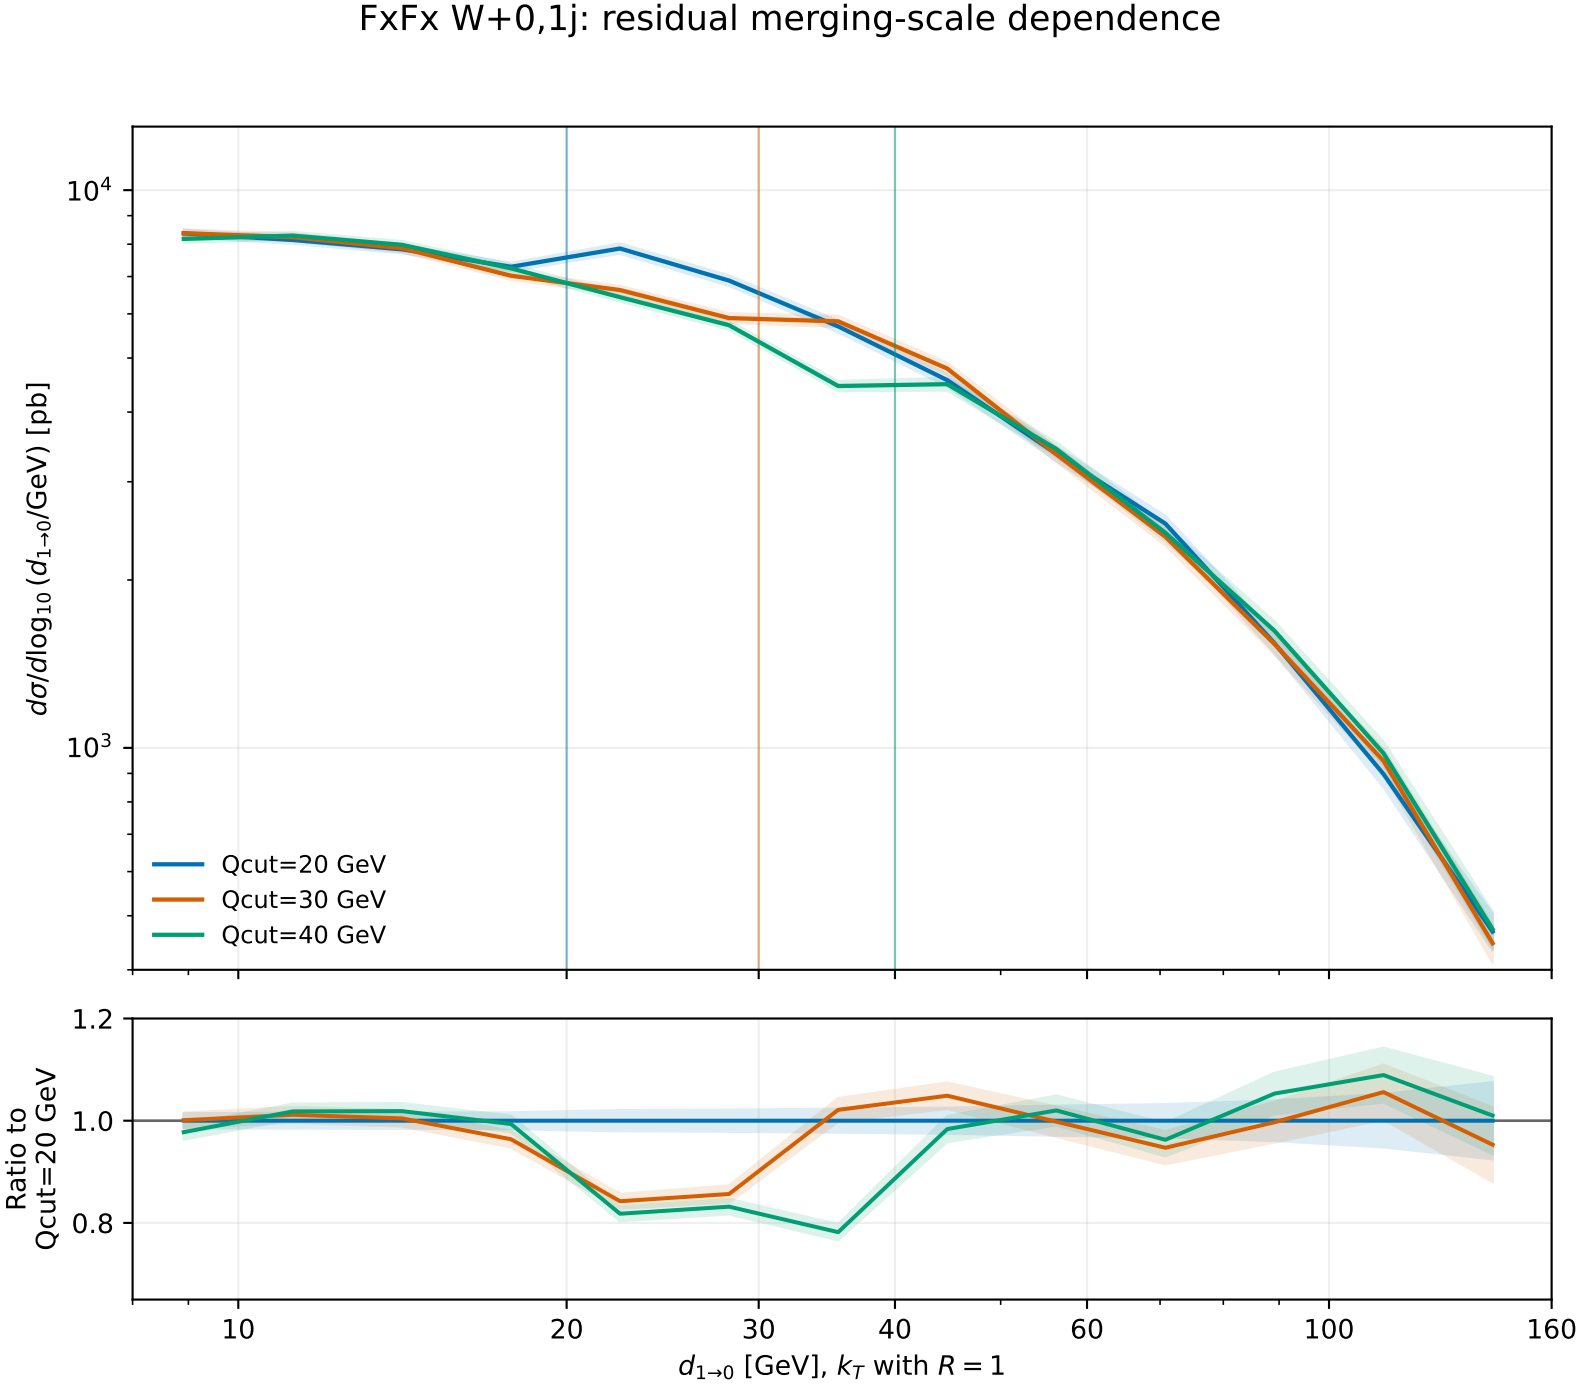
W+1j: the fixed-order FxFx reference uses the wrong counterevent scales

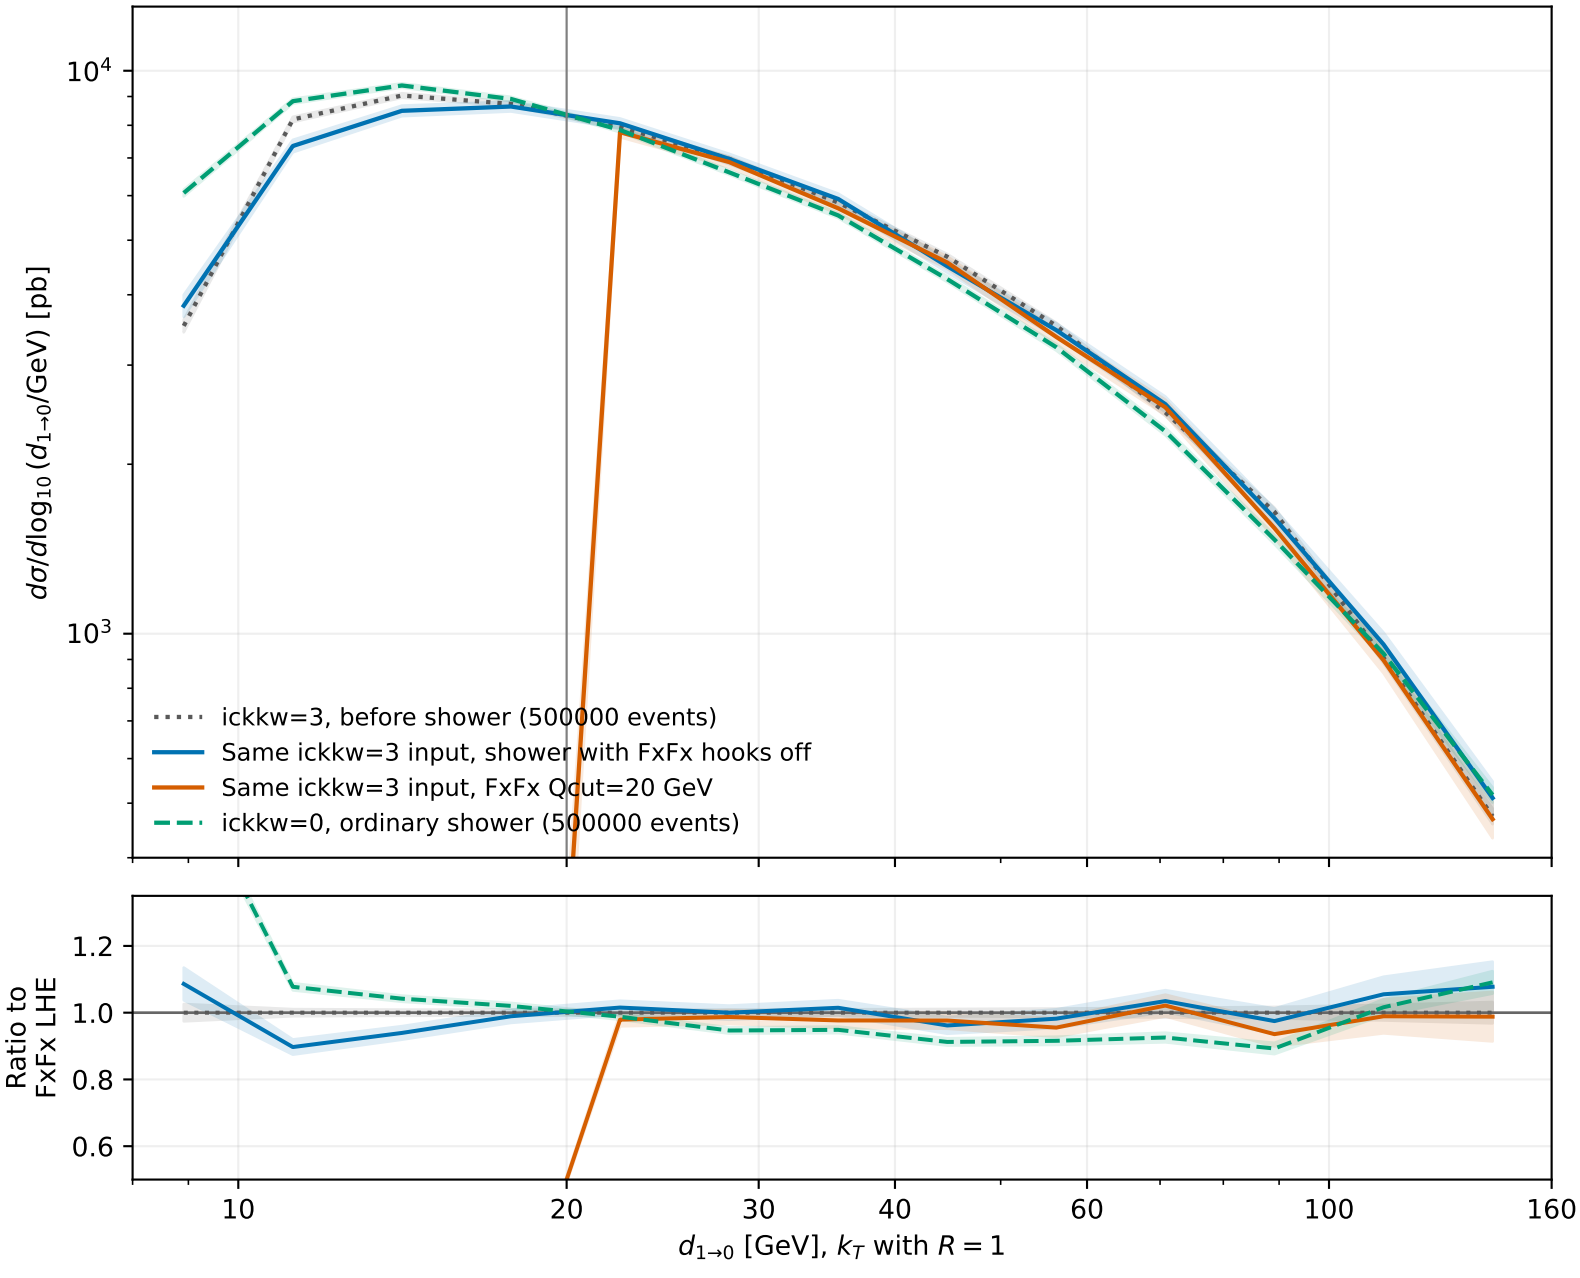


Bands: statistical errors on each numerator. Corrected fixed order: all six subprocesses,
2 x 65536 integration points per subprocess. Original LHE and shower samples: 500000 events.



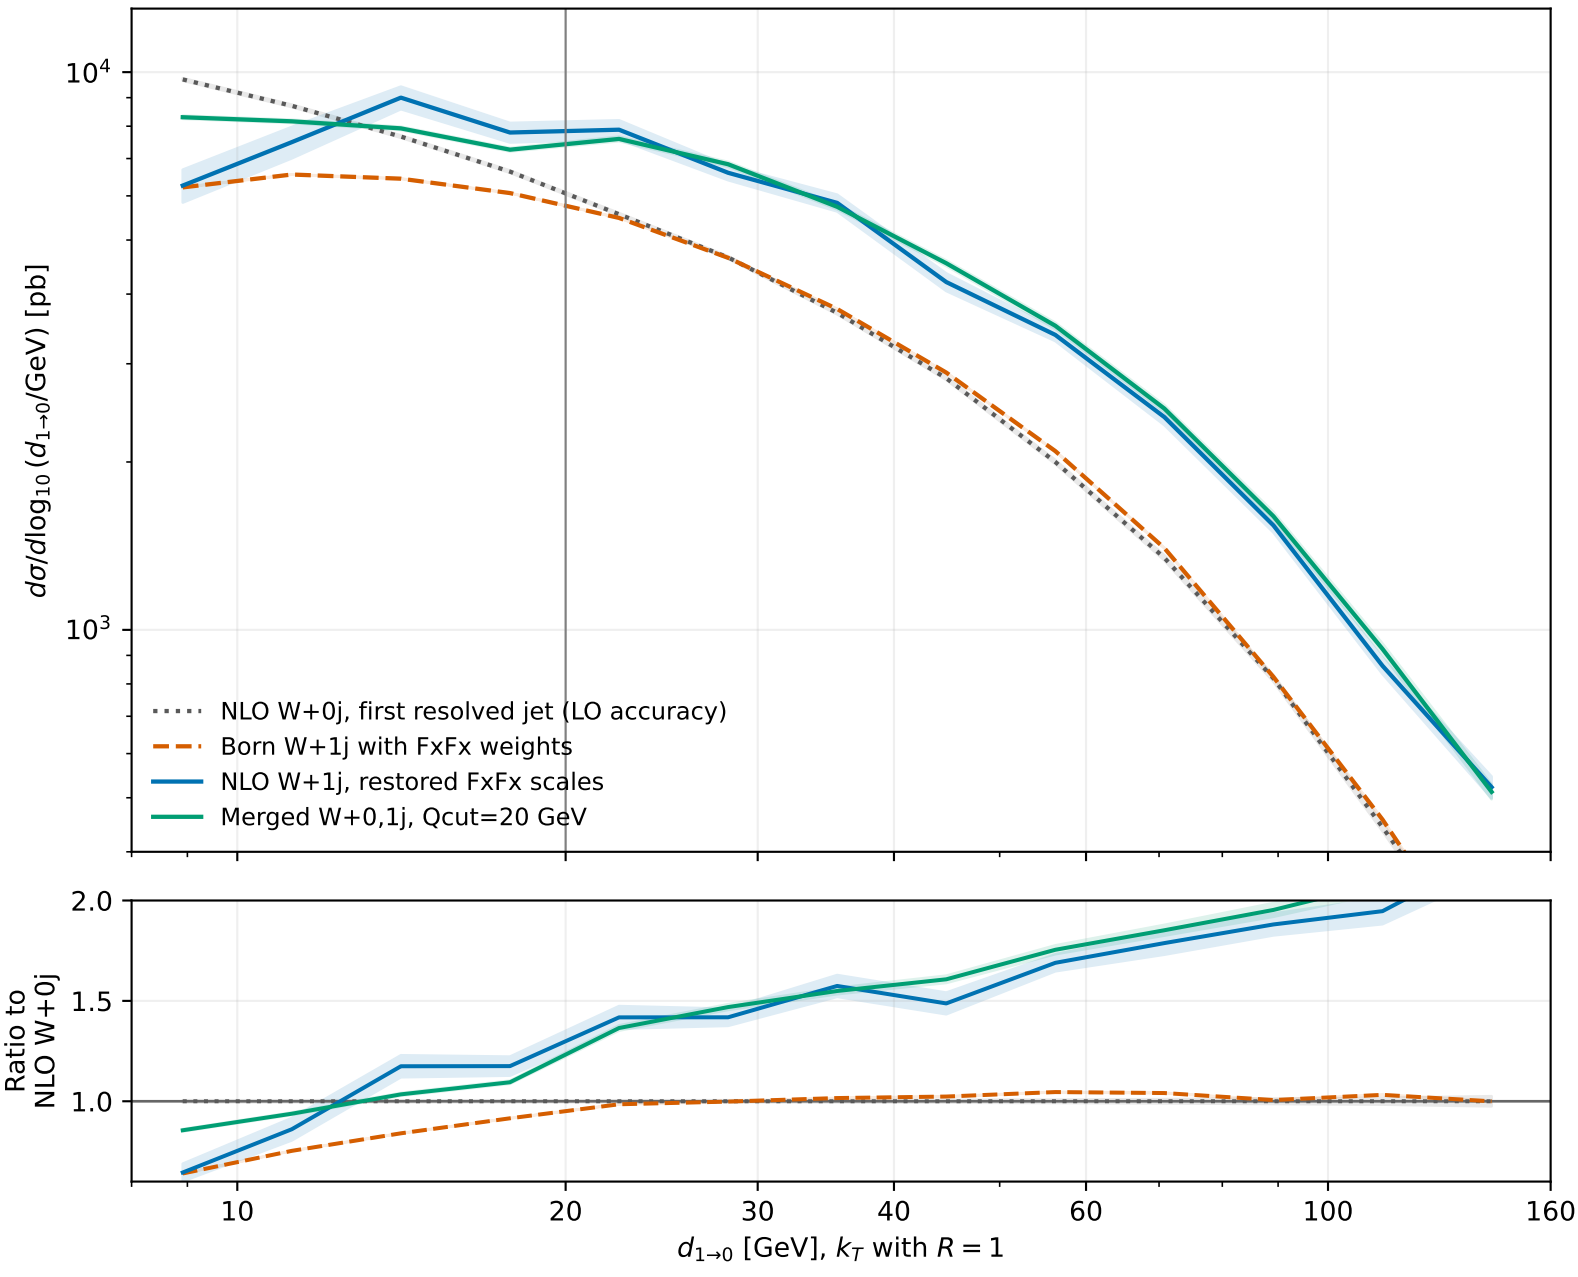
Same FxFx LHE inputs, first 100000 events per multiplicity; Pythia 8.318, random seed 12345.
Generation cut ptj=8 GeV. Ratio bands show numerator errors; scan correlations are not estimated.

W+1j FxFx input: the agreement with an unmerged shower is already present



Reshower controls use 100000 events and random seed 12345; all other shower settings are unchanged.
The merging veto suppresses npNLO=1 below Qcut; it does not explain the low old fixed-order curve.

Near the merging boundary, the two multiplicities differ by the first-jet NLO correction



Correcting the fixed-order reference explains its discrepancy with the one-jet MC@NLO input.
A sizable NLO correction to the first resolved jet remains at scales near the merging boundary.
